Sample Problems and Step-by-Step Solutions

Reviewing sample math olympiad division e problems along with detailed solutions is crucial for understanding problem-solving methodologies. The following examples illustrate typical challenges and approaches employed in Division E.

Sample Problem 1: Algebraic Inequality

Problem: Prove that for all positive real numbers (a, b, c) , the inequality $\left(\frac{a}{b+c} + \frac{b}{a+c} + \frac{c}{a+b}\right) \geq \frac{3}{2}$ holds.

Solution: This classical inequality can be approached using the Nesbitt's inequality. The proof involves applying the rearrangement inequality or employing the AM-HM inequality. Begin by noting that the denominators are sums of the other two variables, ensuring positivity. By symmetry and the known Nesbitt's inequality, the given inequality holds true.

Sample Problem 2: Geometry Proof

Problem: In triangle ABC, the angle bisectors intersect at point I. Prove that the sum of the distances from I to the sides of the triangle equals the inradius.

Solution: The point I is the incenter, and by definition, it is equidistant from all sides of the triangle. The distance from I to each side is exactly the inradius r . Hence, the sum of distances from I to the three sides is $(3r)$. However, the problem might be interpreted as confirming the incenter property by constructing perpendiculars from I to each side and demonstrating their equality. The rigorous proof uses circle tangent properties and angle bisector theorem.

Sample Problem 3: Number Theory

Problem: Find all integer solutions to the equation $x^2 - y^2 = 15$.

Solution: Rewrite the equation as $(x - y)(x + y) = 15$. Since 15 factors into $(\pm 1, \pm 3, \pm 5, \pm 15)$, consider all pairs of integer factors of 15. For each factor pair (a, b) , solve the system $(x - y = a), (x + y = b)$ to find possible (x, y) pairs. Verify which pairs yield integer solutions. The complete solution set includes $(x, y) = (8, 7), (4, 1), (-4, -1), (-8, -7), (4, -1), (8, -7), (-4, 1), (-8, 7)$.
