Overview of the Natural Selection Simulation at PhET

The natural selection simulation at PhET is a digital interactive model designed to demonstrate the process of natural selection in populations of animals. Users can manipulate environmental conditions and observe how traits affecting survival and reproduction change across generations. This simulation emphasizes the role of variation within a population and the impact of environmental pressures on the frequency of advantageous traits. By simulating predator-prey interactions, the tool effectively illustrates how certain phenotypes become more common when they confer a survival benefit. The platform is widely used in educational settings due to its accessibility and ability to visually represent complex evolutionary processes.

Purpose and Design of the Simulation

The primary purpose of the natural selection simulation at PhET is to provide a hands-on learning experience that reinforces theoretical knowledge of evolutionary biology. The simulation is structured around a population of organisms with varying traits, such as color and speed, which influence their likelihood of evading predators. As users modify variables like predator speed or environmental conditions, they can observe changes in trait distributions over multiple generations. This design allows learners to explore concepts such as adaptation, selective pressure, and genetic drift in a controlled virtual environment.

Target Audience and Accessibility

This simulation targets middle school to college-level students studying biology and evolution. Its user-friendly interface and clear visualizations make it accessible for learners at different proficiency levels. The PhET platform ensures compatibility across various devices and operating systems, enabling widespread use in classrooms with diverse technological resources. Additionally, the simulation is free to use, supporting equitable education in evolutionary science.

Key Concepts Illustrated in the Simulation

The natural selection simulation at PhET conveys several foundational concepts central to evolutionary biology. Through interactive experimentation, users deepen their understanding of how natural selection operates in real populations.

Genetic Variation

The simulation highlights genetic variation by presenting populations with individuals exhibiting different traits. These variations are critical for natural selection because they provide the raw material upon which environmental pressures act. Without genetic diversity, adaptation and evolutionary change would be severely limited.

Survival and Reproduction

Survival rates within the simulation depend on how well an organism's traits enable it to avoid predators. Those individuals with advantageous characteristics have higher chances of surviving and reproducing, thereby passing beneficial genes to their offspring. This dynamic emphasizes the differential reproductive success fundamental to natural selection.

Adaptation Over Generations

As generations progress, the simulation demonstrates how populations evolve by increasing the frequency of traits that enhance survival. This gradual adaptation illustrates the cumulative effect of natural selection over time and how environmental factors shape

species characteristics.
