

organic chemistry reactions cheat sheet

Organic chemistry reactions cheat sheet is a valuable tool for students and professionals alike, offering a concise and accessible summary of the myriad reactions that define this intricate field of chemistry. Organic chemistry, the study of carbon-containing compounds, involves understanding how these compounds interact, transform, and form new substances through various chemical reactions. This article will provide a comprehensive overview of the most significant organic chemistry reactions, including their mechanisms, types, and applications, serving as a handy reference for quick revision.

Types of Organic Reactions

Organic reactions can be categorized into several types based on the nature of the reactants, products, and the mechanism involved. The main categories include:

1. Addition Reactions
2. Elimination Reactions
3. Substitution Reactions
4. Rearrangement Reactions
5. Redox Reactions

Addition Reactions

Addition reactions occur when two or more reactants combine to form a single product. These reactions are most common with unsaturated compounds, such as alkenes and alkynes.

- Hydrogenation: The addition of hydrogen (H_2) to alkenes or alkynes, converting them into alkanes.
For example:
- Ethene + $H_2 \rightarrow$ Ethane (using a catalyst like Pd or Pt)
- Halogenation: The addition of halogens (e.g., Cl_2 , Br_2) to alkenes, resulting in dihaloalkanes.
- Propene + $Br_2 \rightarrow$ 1,2-Dibromopropane
- Hydration: The addition of water (H_2O) to alkenes in the presence of an acid catalyst to form alcohols.
- Ethene + $H_2O (H^+) \rightarrow$ Ethanol

Elimination Reactions

Elimination reactions involve the removal of a small molecule from a larger one, typically resulting in the formation of a double or triple bond.

- Dehydrohalogenation: The removal of hydrogen halides (HX) from alkyl halides, yielding alkenes.

- 2-Bromobutane $\rightarrow$ Butene + HBr (using a base like KOH)
- Dehydration: The elimination of water from alcohols, leading to the formation of alkenes.
- Ethanol $\rightarrow$ Ethene + H₂O (in presence of acid)

Substitution Reactions

In substitution reactions, one atom or group in a molecule is replaced by another atom or group. These can be classified into two main types: nucleophilic and electrophilic substitution.

- Nucleophilic Substitution (SN1 & SN2):
 - SN1: A two-step reaction involving carbocation formation. For example:
 - 2-Bromopropane (step 1: forms carbocation, step 2: nucleophile attacks)
 - SN2: A one-step reaction where the nucleophile attacks while the leaving group departs.
 - Methyl bromide + OH⁻ $\rightarrow$ Methanol + Br⁻
- Electrophilic Aromatic Substitution: Involves the substitution of an electrophile for a hydrogen atom on an aromatic ring.
 - Benzene + Br₂ (FeBr₃ catalyst) $\rightarrow$ Bromobenzene

Rearrangement Reactions

Rearrangement reactions occur when a molecule undergoes structural changes to form an isomer. This can involve shifts in the position of atoms or functional groups within the molecule.

- Hydride Shift: Common in carbocation rearrangements. For example:
 - 2-Butyl cation can rearrange to form a more stable 2-pentyl cation.
- Ring Expansion/Contraction: A molecular structure might undergo changes in ring size during rearrangement.
 - Cyclopropyl carbocation can rearrange to form a cyclobutyl cation.

Redox Reactions

Redox (reduction-oxidation) reactions involve the transfer of electrons between substances. In organic chemistry, these often involve changes in the oxidation state of carbon.

- Oxidation: Increasing the oxidation state, often by adding O or removing H.
 - Ethanol $\rightarrow$ Acetaldehyde (by oxidation with KMnO₄)
- Reduction: Decreasing the oxidation state, typically by removing O or adding H.
 - Acetaldehyde $\rightarrow$ Ethanol (by reduction with NaBH₄)

Common Reaction Mechanisms

Understanding the mechanisms of organic reactions is crucial for predicting the outcomes of reactions. The most prevalent mechanisms include:

1. Electrophilic Attack
2. Nucleophilic Attack
3. Radical Mechanism
4. Concerted Mechanism

Electrophilic Attack

In electrophilic reactions, an electrophile (an electron-deficient species) attacks a nucleophile (an electron-rich species).

- Example: In electrophilic aromatic substitution, an electrophile such as NO_2^+ attacks the aromatic ring.

Nucleophilic Attack

In nucleophilic reactions, nucleophiles attack electrophiles, often leading to the formation of new bonds.

- Example: In $\text{S}_\text{N}2$ reactions, a nucleophile directly displaces a leaving group in a single concerted step.

Radical Mechanism

Radical reactions involve species with unpaired electrons, leading to chain reactions.

- Example: The bromination of alkanes via radical substitution:
- Initiation: Formation of bromine radicals ($\text{Br}\cdot$)
- Propagation: $\text{Alkane} + \text{Br}\cdot \rightarrow \text{Alkyl radical} + \text{HBr}$
- Termination: Two radicals combine to form stable products.

Concerted Mechanism

In concerted reactions, bond-making and bond-breaking occur simultaneously, without intermediates.

- Example: The formation of cyclic ethers through a concerted mechanism involving the addition of a nucleophile to an electrophile.

Functional Group Transformations

Functional groups are specific groups of atoms within molecules that are responsible for the characteristic chemical reactions of those molecules. Mastering functional group transformations is vital in organic synthesis.

- Alcohols to Aldehydes: Using oxidizing agents like PCC.
- Aldehydes to Carboxylic Acids: Using stronger oxidizing agents like KMnO_4 .
- Carboxylic Acids to Esters: Via Fischer esterification with alcohols in acidic conditions.
- Esters to Alcohols: By hydrolysis in acidic or basic conditions.
