Understanding the Anatomy of an Apple

Before exploring the details of parts of an apple worksheet, it is important to understand the basic anatomy of an apple. An apple is a type of fruit that belongs to the Rosaceae family and develops from the flowering part of an apple tree. It consists of several distinct parts, each serving a unique function in the fruit's growth and reproduction.

The Skin (Exocarp)

The outermost layer of the apple is called the skin, or exocarp. This thin layer protects the fruit from external damage, pests, and dehydration. The skin also contains pigments that give apples their color, ranging from red, green, to yellow hues depending on the variety.

The Flesh (Mesocarp)

Beneath the skin lies the flesh, also known as the mesocarp. This juicy, edible part of the apple is rich in vitamins, fiber, and natural sugars. The flesh provides nourishment and serves as the primary source of energy for animals and humans who consume the fruit.

The Core (Endocarp) and Seeds

At the center of the apple is the core, or endocarp, which houses the seeds. The core is typically fibrous and less palatable than the flesh. The seeds contained within the core are responsible for reproduction, allowing new apple trees to grow when planted.

The Stem and Calyx

The stem connects the apple to the tree, facilitating the transfer of nutrients and water necessary for the apple's development. On the opposite end of the stem is the calyx, composed of sepals, which protects the developing fruit during its early stages.
