Understanding Restriction Enzymes

Restriction enzymes, also known as restriction endonucleases, are proteins that recognize specific sequences of nucleotides in DNA and cleave the DNA at or near these sites. These enzymes serve as molecular scissors in genetic engineering, enabling scientists to cut DNA molecules into smaller fragments for analysis or recombination.

Types of Restriction Enzymes

Restriction enzymes are classified into several types based on their structure and cleavage patterns. The most commonly used in laboratories are Type II restriction enzymes, which cut DNA at specific palindromic sequences.

- **Type I:** Cut DNA at random sites far from the recognition sequence.
- **Type II:** Cut within or near the recognition site; highly specific and widely used.

- **Type III:** Cut a short distance away from the recognition site.

Recognition Sites and Cleavage Patterns

Each restriction enzyme recognizes a particular nucleotide sequence, typically 4-8 base pairs long. The cleavage can result in blunt ends or sticky ends, which affect how DNA fragments can be joined during cloning processes.
